AUTHOR: Imbritskiy, M.I., Engineer.

TITLE: Damage to steam and water fittings in power stations. (Fovrezhdeniya parovodyanoy armatury na elektrostantsiyakh.)

PERIODICAL: "Elektricheskie Stantsii" (Power Stations), 1957, Vol.28, No.2, pp. 21 - 25 (U.S.S.R.)

ABSTRACT: Although the quality of fittings produced has recently improved some of them are still not good enough. In the power stations of the Moscow system in 1955 there were 11 accidents and 98 cases of scrapping equipment because of damage to fittings. In one high pressure power station in the first year of operation two boilers had to be stopped 11 times. This all occurred because of defects of design, erection and operation and defects associated with poor quality repairs. The article describes the defects of design with particular reference to steam valves and explains with drawings how these are being corrected. Defects associated with poor quality of repairs are then discussed - this is mainly concerned with the organisation of repair work. Defects of erection and operations are also described. It is concluded that fittings factories should improve the quality of production of control and safety valves taking advantage of the experience of power stations. Power systems should organise the centralised repair of fittings at

Card 1/2

Damage to steam and water fittings in power stations. (Cont.)
special repair works or in power station workshops. Special
designs of fittings repair workshops should be got out. Special
courses on the repair of fittings should be instituted in power
systems. Existing instructions on the repair of fittings are
largely inadequate and they should be rewritten. If fittings
appear to be undamaged they should not be dismantled for ins-
pection before erection.

TITLE: Gasket Sealings for Fittings in Power Plants
(Sal'nikovyye uplotneniya armatury na elektro-
stantsiyakh)

PERIODICAL: Energetik, 1959, Nr 3, pp 21-25 (USSR)

ABSTRACT: The author describes various types of gasket sealings currently used for fittings used in Soviet power plants. The sealings most often used consist of a mixture of 60-70% graphite and 40-30% asbestos flakes, and are called "Pushonka". Other popular sealings are of graphite and asbestos rings placed alternately and pressed. In conclusion, the author gives practical instructions for installing new packings. There are 5 diagrams.

was observed not to be necessarily accompanied by an in-
crease or decrease in the amount of carotin. In arhizoma-
tous wheat grass, bulbous barley, and perennial forms of
rye, the maximum quantity of chlorophyll was present during
the stages of tillering, tube-formation and earing; in the
crested wheat grass and meadow timothy the chlorophyll con-
tent increased until the stage of tube-formation. The max-
imum content of carotin (in milligrams/kg) was observed in
winter wheat (663), bulbous barley (559), perennial forms
of rye (505-580), dew grass (542), tall oatgrass (510),
crested wheat grass (216-402). Bibliography with 15 titles.

TITLE: Determination of the dynamic characteristics using a discrete correlation computer

SOURCE: AN GruzSSR. Institut elektroniki, avtomatiki i telemekhaniki. Elementy vychislitel'noy tekhniki i mashinnyy perevod (Elements of computer technology and machine translation). Tiflis, Izd-vo Metsniyereba, 1964, 71-84

TOPIC TAGS: correlation function, data processing system, data correlation

ABSTRACT: The article discusses the various computer methods of determining the correlation function by means of a convolution-type integral of the form

$$R_{yx}(s) = \int_0^{\infty} R_{xx}(s - \sigma)k(\sigma)d\sigma,$$

where R_{yx} is the mutual correlation function, R_{xx} the autocorrelation function, and $K(\sigma)$ the impulse transfer function of the system. It is shown that the combined use of the Fourier transformation and of a special computer (discrete correlograph) offers many advantages over other methods. The correlograph itself was developed at the Institut elektroniki, avtomatiki i telemekhaniki (Institute of

Card 1/2

L 00470-66

Electronics, Automation, and Telemechanics) AN GrunSSR and was described elsewhere by two of the authors (Imedadze and Sasyan, with N. S. Chakhrov, Diskretnyy korrelograf [Discrete Correlograph], Izdaniye TsITEN, No. 22, Moscow, 1961). The processing of the primary information for the determination of the impulse transfer function with this correlograph consists of three stages. The first involves the determination of the correlation functions from the primary information. The second consists of calculating the spectral densities, the real frequency characteristic, and the imaginary frequency characteristic of the system. The third stage consists of finding the transfer function itself. The mathematics and the required computer programming are described in some detail, and some illustrative examples pertaining to the control of a blast furnace are included. The calculation results were in satisfactory agreement with the actual data. Orig. art. has: 13 figures and 16 formulas.

where $R_{xx}(\tau)$ is the autocorrelation input function; $R_{yx}(\tau)$ is the mutual correlation function between the input and output of the system, and $k(\theta)$ is the pulsed transfer function. This equation can be solved by means of Fourier transforms (V. V. Solodovnikov, A.S. Uskov, Avtomatika i telemekhanika, 1959, no. 12), and the necessary calculative manipulations can be carried out on the discrete

TITLE: Some problems in evaluation of accuracy of correlation functions

SOURCE: AN GruzSSR. Institut elektroniki, avtomatiki i telemekhaniki. Skhemy avtomaticheskogo upravleniya (Automatic control circuits). Tiflis, Izd-vo Metsniyereba, 1965, 34-39

TOPIC TAGS: correlation function, correlation statistics

ABSTRACT: Further improvement in the methods of calculating correlation functions, with the source information in discrete form, should go along these two directions: (1) Development of methods for evaluating the error depending on the number of points of source information; with knowledge of the process frequency spectrum available, the highest-frequency region should contain 10-40 points; (2) With a sufficiently large number of source-information points, the accuracy of calculation of correlation function should be determined. The present article places particular emphasis on the

Card 1/2

L 01038-67

ACC NR: AT6015125

4

case of a relatively small number of the source-information points. A formula for the centered autocorrelation function indicates two sources of errors: (a) level quantization and (b) determination of mathematical expectation. If the quantization interval is $q = 1/31$ maximum level, the quantization error is negligible. For practical purposes, it is recommended that estimation of the mathematical expectation be restricted to the second decimal place. With the above provisions, the correlation functions of interdependent parameters (30—70 points) of the rolling process at the Pervoural'sk Pipe Plant were estimated on a DK-1²⁰ digital correlograph developed by the Institute of Electronics, Automatics and Telemechanics, AN GruzSSR. TOPIC TAGS: buildup factor, attenuation function, dose data, radiation source parameter, radiation protection, radiation shielding, radiation source, shielding material, nuclear radiation

PURPOSE AND COVERAGE: This book is intended for engineers-physicists specializing in the calculation of reactor shielding, and for the engineering and scientific community working with radioactive sources. The book gives information on calculations and graphs, and tabulated data, necessary for calculating the shielding against radioactive radiation of extended sources of various geometries. The book is based on data published in Soviet and other literature and on that obtained by the present authors. The authors thank M. V. Imendayeva.

A		In high-temperature reheating furnaces excellent results are obtained with injector-type burners in which the combustion air is introduced into the gas stream. In this connection the use of a gas of low caloric value is of special interest. (Abstract from Steel, no. 4, 1946, p. 124-126.)	
METALLURGICAL LITERATURE CLASSIFICATION		16-77	

1467. **CONTINUOUS FURNACE HEATED BY HIGH CALORIFIC GAS** (Steel (Steel, Wilson), 1933, 13, 27-28). Continuous furnace design for working on poor gas is discussed. Heat results are at present being obtained with blast furnace gas-fired types having ceramic and metal recuperators for air and gas, respectively, and injector burners. For gas with calorific value 1500-2200 kcal/cu.m only the air requires a recuperator. Such results are due to the improvement of injection burner design, increasing the range of automatic control to include gases of 2200 kcal/cu.m, and metal recuperators must be produced for heating air to 600°C by combustion products at 1100°C.

TITLE: Application of the theory of functions of a complex variable to the solution of statically indeterminate problems of momentless theory of a spherical shell

SOURCE: Teoriya plastin i obolochek; trudy II Vsesoyuznoy konferentsii, L'vov, 15-21 sentyabrya 1961 g. Kiev, Izd-vo AN USSR, 1962, 94-96

TEXT: The author considers an elastic spherical shell with a hole, clamped along the edge, with a concentrated force acting at a certain point of the shell. In order to avoid the inconsistency in the boundary conditions, the author divides them into tangential and non-tangential conditions, and proposes that the former should be adjusted with the aid of momentless theory, the latter with the aid of the edge effect. It is stated that this possibility has been verified by expanding the unknown stress and displacement into series; it was found that an iteration process can be constructed in

TITLE:

Methods of Preparation of Chamber Bottoms and Pillars (Sposoby podgotovki dnishch kamer i blokov)

PERIODICAL:

Gornyy Zhurnal, 1957, No 12, pp 3-8 (USSR)

ABSTRACT:

The Zyryanovsk Lead Combine mines from the thick steep-sloping deposits of very hard ore by breaking off the ore with deep blast holes. The author describes several mining systems used in various ore mines and then dwells on the trench undercutting of chambers which is the system used in the Zyryanovsk mine of the Zyryanovsk Lead Combine. Citing some technical and economical indices of this system the author draws the following conclusions:

1. The trench undercutting method is more efficient than the undercutting with formation of funnels; moreover, the costs of development opening are reduced.
2. The formation of trenches by horizontal bore holes is more economical than their formation by vertical fan-shaped sets of holes; in addition to this, it achieves more regular outlines of the trenches which facilitate the subsequent breaking off

Card 1/2

Methods of Preparation of Chamber Bottoms and Pillars

127-12-1/28

the ore in the chambers.

3. The rectangular shape is the best suited for the trench
orts.

4. Slopes for the ore outlet with an incline of 50 to 60° are
better than vertical ones.

5. If the ore is sufficiently rigid, it is expedient to make
wide slits instead of slopes in the trench undercutting system.

6. Funnels formed by means of blasting are to be advanced from
below upward for the entire cross section at once.

The article contains 7 figures, and 2 tables.

Tsarenkov, B. V.

TITLE: Alloyed GaAs junction diodes

PERIODICAL: Fizika tverdogo tela, v. 3, no. 3, 1961, 991-994

TEXT: This is the continuation of Refs. 1-9 which the authors published in FTT with the exception of Ref. 9 (G. T. Sah, R. N. Noyce, W. Shockley, Proc. IRE, 45, 9, 1228, 1957). The diodes studied were made from thin plates of n-type GaAs single crystals which had been grown by the method of Chokhral'skiy. Their resistivity was 0.02 ohm-cm, their electron concentration $\leq 10^{17} \text{ cm}^{-3}$, and their mobility $3500 \text{ cm}^2/\text{v}\cdot\text{sec}$ at room temperature. The p-n junction was obtained by introduction of molten zinc or from the eutectic Au-Zn alloy. Lead served as non-rectifying base contact. The area of the p-n junction was equal to $S = 0.005 \text{ cm}^2$. The volt-ampere characteristics of such a diode at 25 and 300°C are shown in a figure. They were recorded by the "characteriograph" described in Ref. 10 (Tsarenkov, PTE, No. 2, 144,

Card 1/6

Alloyed GaAs ...

1960). The most important results were the following: 1) The direct branch of the diode characteristic at voltages below the cutoff voltage can be described by the formula $I_{dir} = I_0 [\exp(qU_{dir}/\beta kT) - 1]$ (1). I_{dir} is the direct current density, U_{dir} the direct voltage drop on the diode, and β a dimensionless factor. I_0 increases with rising temperature. Within the range of nitrogen temperatures to room temperature, $I_0(T)$ is a weak function (weaker than at higher temperatures). At room temperature, $I_0 \approx 10^{-8} - 10^{-7}$ a/cm², and at 300°C, $I_0 \approx 10^{-5} - 10^{-4}$ a/cm². β decreases with rising temperature within the range of -196-+300°C. At nitrogen temperatures, $\beta \approx 7 - 12$; at room temperature, 2 - 3; and on a further change in temperature, it approaches a value ≈ 2 . The direct branches of the volt-ampere characteristics of several diodes have two exponential sections: $I'_{dir} = I_{01} \exp(qU'_{dir}/\beta_1 kT)$ and $I''_{dir} = I_{02} \exp(qU''_{dir}/\beta_2 kT)$; $U'_{dir} < U''_{dir}$, $I_{01} \gg I_{02}$, $\beta_1 > \beta_2$. I_{01} and I_{02} increase with temperature (I_{02} faster than I_{01}); at 200-300°C, $I_{01} \approx I_{02}$, $\beta_1 \approx \beta_2$. The occurrence of two

Card 2/6

20802

S/181/61/003/003/029/030
B102/B205

Alloyed GaAs ...

exponential sections of the direct branch is related to the surface properties of the diode. By a change of the composition of the etching agent, one of them disappears, and in formula (1) $I_{\infty} \approx I_{02}$ and $\beta \approx \beta_2$. The existence of two sections and the disappearance of one section by surface treatment is ascribed to the fact that the surface of gallium arsenide has an inverse layer. The cutoff voltage of the direct branch is lower than the contact voltage calculated according to Shockley's junction theory, and drops with increasing temperature. The temperature coefficients of the two voltages are almost equal. The curvature G_8 of the linear section of the direct branch calculated from the data of the diode with a base 0.5 mm thick amounted to $\sim 10^3$ a/v·cm². The differential resistance at zero voltage can be exactly calculated from the formula $R_0 = \beta kT/qI_0$. $R_0(T)$ is nearly inverse to $I_0(T)$. R_0 of diodes with two exponential sections of the direct branch is much smaller than R_0 of diodes with only one section. The reverse branch of the characteristics at voltages lower than the breakdown voltage can be described by the empirical formula $I_{rev} = AU_{rev}^n$, where $n \leq 1$; I_{rev} increases with temperature. The breakdown voltage also increases with temperature, which is

TITLE: Electrical properties of pn tunnel junctions in gallium
arsenide

SOURCE: Fizika tverdogo tela, v. 6, no. 8, 1964, 2281-2288

TOPIC TAGS: gallium arsenide diode, pn junction, single crystal,
tunnel current, temperature dependence, forbidden band

ABSTRACT: Forward and reverse branches of the current-voltage characteristics of p-n tunnel junctions in GaAs were investigated between 77 and 425K. The junctions (10^{-5} cm² in area) were produced in single-crystal Zn-doped p-type material by alloying with tin. Direct current or voltage pulses (to avoid heating) were used. The forward (tunnel and recombination) current rose rapidly to a

Card 1/3

L 18849-65

ACCESSION NR: AP4043341

maximum at 0.1 V; this was followed by an exponential fall of the current ($I \sim \exp(-qU/\mathcal{E}_1)$) nearly to zero at 0.5--0.7 V and an exponential rise ($I \sim \exp(qU/\mathcal{E}_2)$) on further increase of the voltage. The values of \mathcal{E}_1 and \mathcal{E}_2 were independent of temperature, which indicated the presence of levels in the forbidden band. The forward current was little affected by temperature due to a weak temperature dependence of the tunnel transition probability and of the Fermi function. The Fermi level at room temperature was $\zeta_p = 0.08$ -- 0.15 eV for the p-region and $\zeta_n = 0.26$ -- 0.32 eV for the n-region. The reverse tunnel current increased, linearly at $U \ll (\zeta_{p,n}/q)$ and quadratically at $U > (\zeta_{p,n}/q)$, with rise of the voltage across the junction. This indicated that at energies $\mathcal{E} \gtrsim \zeta_{p,n}$ the band involved in the reverse tunnel current was parabolic. The reverse

Card 2/3

L 18849-65

ACCESSION NR: AP4043341

current varied very little with temperature, again due to a weak temperature dependence of the tunnel transition probability and of the Fermi function. "The authors are grateful to F. Kh. Kreyndel' and G. V. Kuznetsova for help with the work and to R. P. Kazarinov for a discussion of the results." Orig. art. has: 6 figures and 5 formulas.

TITLE: Recombination radiation in GaAs tunnel p-n junctions

SOURCE: Izika i tekhnika, v. 7, no. 2, 1965, 634-636

TOPIC TAGS: tunnel effect, tunnel p n junction, p n junction, recombination radiation, recombination, gallium arsenide

ABSTRACT: The dependence of the integral intensity of radiation Φ on the current I in the range of current densities $50-10^4$ amp/cm² can be represented in the form of the sum of two members $\Phi = \Phi_2 + \Phi_1 = A(T)I^n + \dots$ (T, I), where the member $\Phi_2(T, I)$ is the part of the radiation intensity which is added to the intensity Φ_1 . The fact that at a certain voltage the radiation intensity and the curve of the dependence of the radiation intensity on voltage display a "hump" indicates that the recombination radiation in tunnel transitions contribute to the total radiation. The findings of other researchers (e.g., Anderson, R., Proc. IEEE, 51, 1963, 610), no radiation in the region of

TOPIC TAGS: gallium arsenide, semiconductor, electroluminescence, p-n junction, recombination radiation, radiative recombination

ABSTRACT: An investigation was made of the injection electroluminescence of GaAs. Experimental results are at temperatures of 77 and 293K. In preparing the diodes, zinc was diffused into an epitaxial GaAs monocrystal up to hole concentration of $2.5 \cdot 10^{17} \text{ cm}^{-3}$ in a $10\text{-}20$ micron surface layer. The tunnel p-n junction was fabricated by diffusing tin into the p-side of GaAs. The emission was found to vary with temperature. The recombination radiation spectrum showed a temperature dependence. The emission was directed toward higher photon energies with increasing temperature. The spectral dependence of the injection current was also investigated. The results are compared with theoretical calculations.

Card 1/2

ACCESSION No. AP000-86

than $1-2 \cdot 10^4$ amp/cm² electroluminescence depends on the properties of tunnel diodes, the current independence of the intensity is determined by the properties of the p-n junction. The current independence of the intensity is attributed to tunnelling of electrons into the lying levels in the forbidden band and subsequent radiative recombination. Orig. art. has 6 figures.

TITLE: Electron-hole transition in a strongly degenerate semiconductor at very high current densities

SOURCE: Fizika tverdogo tela, v. 7, no. 5, 1965, 1480-1489

TOPIC TAGS: pn junction, degenerate semiconductor, current voltage characteristic, tunnel diode, recombination zone, gallium arsenide, carrier mobility, carrier life-

ABSTRACT: Formulas are derived for the current-voltage characteristics and for the width of the minority non-equilibrium carrier recombination region in p-n junctions with strong degeneracy of the minority carriers and very large current densities. It is shown that the recombination current density is proportional to the square of the current density. The formulas derived make it possible to determine the current-voltage characteristics by a null method using pulses 2.4-10 μ sec in dura-

Card 1/2

1-52605-85
ACCESSION NR: AP:012561

tion. An expression $I \sim (U_p - U_0)^n$ is obtained for the dependence of the forward current on the potential-diode voltage, with n depending on the mechanism whereby the non-equilibrium carriers are scattered. This formula was confirmed experimentally in the tunnel diodes at current density $(1.5-50) \times 10^4$ amp/cm² and at temperatures 77-425K. The width of the recombination region is found to depend on the injection level and to have the form $l \sim (U_p - U_0)^{3/2}$. The mobility of the non-equilibrium electrons in the p region is 100-300 cm²/v-sec, and the lifetime is $(1-4) \times 10^{-9}$ sec at room temperature. At very large current densities the af-

fective contact potential difference is found to be lower than given by the difference between the Fermi levels of the p and n regions. The barrier height ϕ_b is the barrier potential and the effective contact potential difference ϕ_{eff} is the difference between the Fermi levels of the p and n regions. The results of the experiments are in good agreement with the theoretical calculations.

TITLE: The effect of impurities on the recombination radiation of gallium arsenide

SOURCE: Fizika tverdogo tela, v. 7, no. 10, 1965, 3115-3118

TOPIC TAGS: recombination radiation, gallium arsenide, pn junction, impurity, acceptor, donor

ABSTRACT: The effect of Zn, Cd, Mn, and Fe impurities on the recombination radiation of GaAs p-n junctions was experimentally investigated. The junctions were formed by direct diffusion of the element, by simultaneous diffusion of Mn and Cd and Fe and Cd, or by diffusion of Mn and then Cd, or Fe and then Cd into n-type GaAs with an electron concentration (N_n) of $5 \times 10^{16} - 3 \times 10^{18} \text{ cm}^{-3}$ (crystals with $N_n > 7 \times 10^{17} \text{ cm}^{-3}$ were doped with Te). The junction area was $10^{-3} - 10^{-4} \text{ cm}^2$. The recombination spectra were measured at 77 and 293K in the photon energy range between 0.7 and 1.6 eV. The spectra were recorded at direct injection currents at which the energy of the short wavelength band was independent of the current. The experimental data are given in Fig. 1 and Table 1. The band with $h\nu_{\text{max}} \approx 1.01 \text{ eV}$ (77K) and $h\nu_{\text{max}} = 0.95 - 0.98 \text{ eV}$

TITLE: Optical and photoelectric properties of single-crystal ZnSiP_2

SOURCE: AN SSSR. Doklady, v. 163, no. 3, 1965, 606-608

TOPIC TAGS: optical property, photoelectric property, zinc compound optic material, forbidden band, light polarization, absorption edge, temperature dependence

ABSTRACT: In view of the lack of published data on this compound, the authors have studied the photoelectric and optical properties of n-type single crystals obtained from the gas phase by the method of gas-transport reactions. The spectral sensitivity of the photoconductivity was measured at 77 and 300K using a setup comprising a tungsten incandescent lamp, a light interrupter, a monochromator (IKS-21), amplifier (V2-6), synchronous detector, and electronic potentiometer (EPP-C9). The absorption spectrum was measured with the spectrograph and a camera at 300, 77, and 4.2K. In addition, the authors investigated the influence of polarization of the incident light on both the optical and photoelectrical properties. Photoconductivity was observed at incident photon energies 0.5-2.5 ev. At 300K the photoconductivity has a highly peaked maximum at 2.14 ev, and also maxima at 0.8 and 1.0

ev, attributed to impurities. At 77K the maxima shift to 2.19, 1.04, and 0.84 respectively. The spectral photoconductivity curve exhibited also some kinks due to transitions of the electrons from the valence to the conduction band. Polarization began to affect the photoconductivity only above 2 ev, when the photoconductivity became highly sensitive to the direction of the electric vector. This may be due to anisotropy of the crystal. Not all crystals showed a sharp absorption edge, a fact attributed to the number of crystal defects. Where a sharp absorption edge was observed, it showed a dependence on the temperature and on the polarization. The maxima of the photoconductivity and the start of the strong optical absorption were very close to each other, and the sharpness of the absorption edge suggests the presence of direct interband transitions in $ZnSiP_2$. The forbidden band is estimated at 2.13 ev at 300K and between 2.2 and 2.25 ev at 77K. Two absorption bands are observed at 2.23 and 2.27 ev at 77 and 4.2K, and their origin is not clear. This report was presented by L. A. Artsimovich. Orig. art. has: 2 figures and 1 table.

TITLE: Kinetics of radiative recombination of nonequilibrium carriers in GaAs p-n junctions

SOURCE: Fizika tverdogo tela, v. 8, no. 7, 1966, 2098-2103

TOPIC TAGS: gallium arsenide, radiative recombination, semiconductor carrier, pn junction, relaxation process, spectral distribution, radiation intensity

ABSTRACT: The authors report results of experiments on the dependences, on the current density, of the intensity of radiation for different bands of the spectrum (photon energy range 0.7 - 1.5 eV) of GaAs diffusion p-n junctions, at 77 and 293K, and also results of a simultaneous investigation of the relaxation of the radiation intensity when rectangular current pulses are passed through the junction. The relaxation study is a continuation of earlier work by the authors (Abstracts of Papers of Second All-Union Conference on p-n Junctions, AN LatSSR, Riga, 1964, p. 14) where a long-wave aftereffect was noted after the termination of a square pulse. The GaAs p-n junctions were obtained by diffusion of Zn, Cd, or Cd and Mn jointly. The tests consisted of determining the spectral distribution of the radiation intensity, the variation of the radiation intensity with the current, and oscillograms of the current, voltage, and

Card 1/2

3
radiation-intensity pulses. The current pulses ranged in amplitude from 0.05 to 7 amp and in duration from 10 to 100 μ sec. Pulses with duration ~ 10 nsec were also used. The spectrum consisted of several bands, the presence of which indicates that the recombination of the nonequilibrium carriers goes in part through deep levels. The possible kinetics of such a process are discussed. The current and voltage relaxation time is several orders of magnitude shorter than the intensity relaxation time of the long-wave radiation. The bands with longer wavelength have longer relaxation times. The two bands with the longest wavelength are attributed to recombination of the minority carriers injected over the potential barrier and captured at deep levels. The authors thank O. V. Konstantinov, V. I. Perel', and A. L. Efros for a discussion of the results. Orig. art. has: 4 figures.
